The Tower Blueprint

How a tower that doesn't exist yet ends up looking like this.

This tower doesn't exist

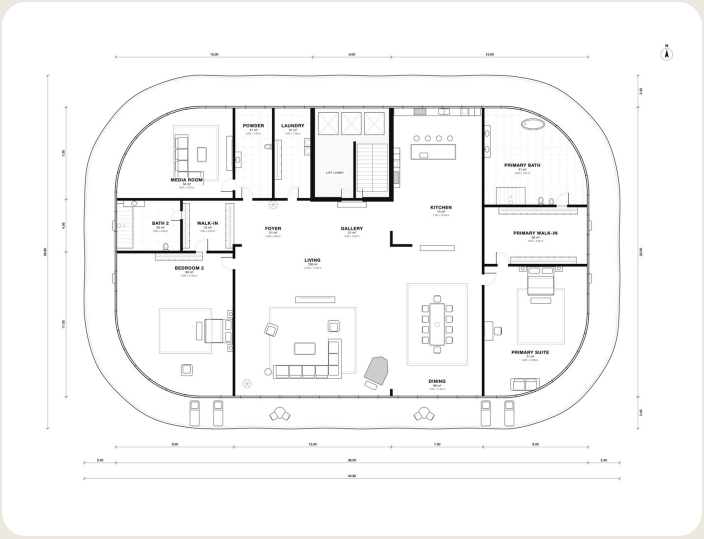

SAMAR, Dubai Marina: 23 floors on the water, the marina below and the skyline behind. Nobody has poured a slab yet, and this is already what buyers see.

Prompt — Nano Banana Pro

```
Image 1 is the 3D: keep the camera, the floors, the balconies and the crown exactly as they are. Floor-to-ceiling glass with a light bronze tint, white curved slab edges with a thin warm light line, clear glass balcony rails, as in image 2. At the base a double-height glass lobby, palms and the marina with white yachts. Behind, the Dubai Marina skyline: the grey boxes become the real towers. Sun just below the horizon on the left, the first windows lit. Editorial architecture photograph, natural colour, fine film grain.
```

→ Ready to paste: the 3D screenshot as image 1, a photo of the materials as image 2.

It started as a plan

Lines and a few room measurements, the same drawing every developer has on the desk, and the one buyers can’t picture themselves in.

Then a 3D in the browser

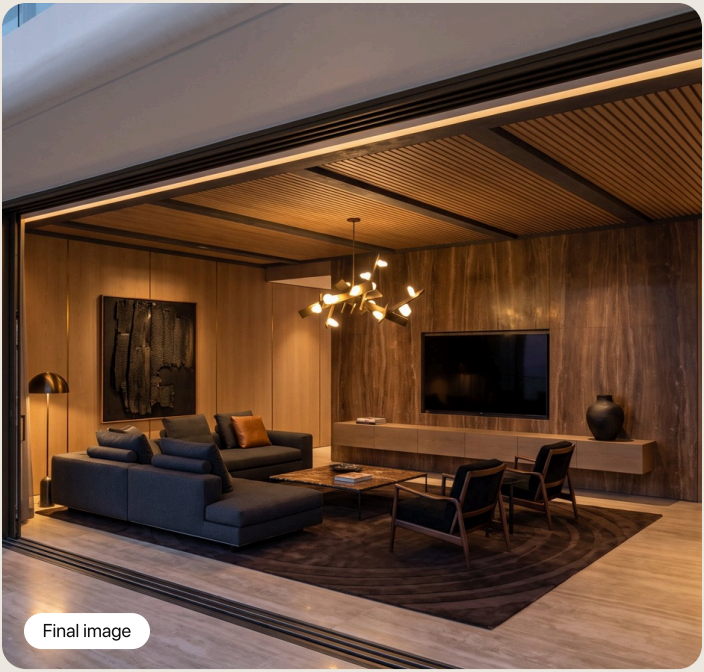

3D model

Claude builds it from that plan, floor by floor and in real metres, so every wall and every window sits where the architect drew it.

Prompt — Claude

```
Build a 3D massing model in three.js, in real metres, from the floor plan in this folder. One tower of 23 levels on the water: a 7.2 m double-height lobby, floors at 3.6 m, a 4.8 m penthouse and a 5 m crown with a flat roof that overhangs. Slabs of 40.8 × 26.8 m with rounded ends and the glass set back to 36 × 22 m, so every floor has a deep balcony all round. A thin line at every slab. The marina in front and the neighbouring towers as plain grey boxes at their real heights. Camera 450 m away across the water, at 40 m, 70 mm, vertical lines straight.
```

Then the photo

The same 3D and the same camera, and now a living room you could move into tonight.

Four things decide if it looks real

The numbers

Floors times 3.3 to 3.5 m, plus the podium and the crown: get the height right before any material goes on.

The camera

Far and low, a few hundred metres away with a 50 to 85 mm lens, so the tower stands straight.

Three parts

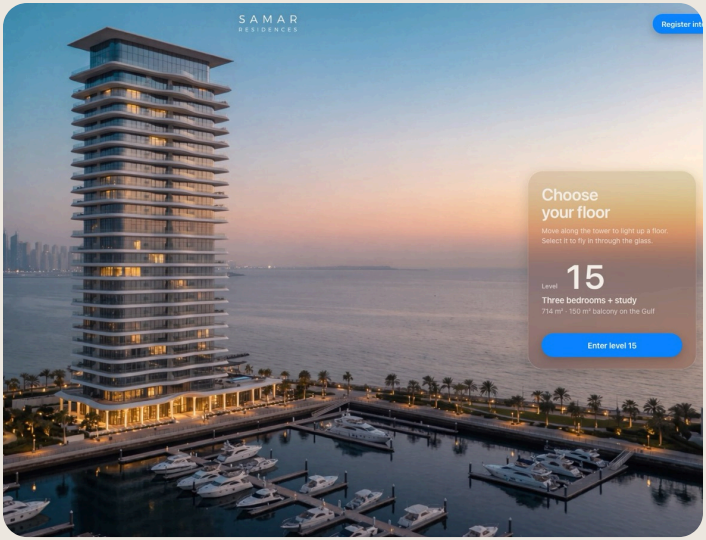

Crown, body and podium, each one named with its own material and colour.

The check

Count the floors against the 3D; if one is wrong, generate again from the 3D, never fix the picture.

All four, with the checks we run before we send anything, are in the Full Tower Blueprint.

Then they pick the floor

On the SAMAR site the buyer moves over the tower, chooses floor 15, flies in through the glass and walks from the terrace to the bathroom.

HOW WE DID IT

On Seedance, the tower seen from far away is the start frame and the terrace of floor 15 is the end frame, with one slow move written in the prompt: the camera flies forward and rises a little, steady, no cuts. Then every next clip, on Kling, starts from the exact last frame of the one before, so the whole visit plays like a single shot.

You've seen it now build your own

01 What you are building, and why it sells

02 The shot list, before you generate anything

03 The clips, one start frame at a time

04 The way back, without generating anything

05 Tracing the floors on the first frame

06 The floor picker: panel, hover and click

07 The building and the apartment

08 The player, so nothing stalls

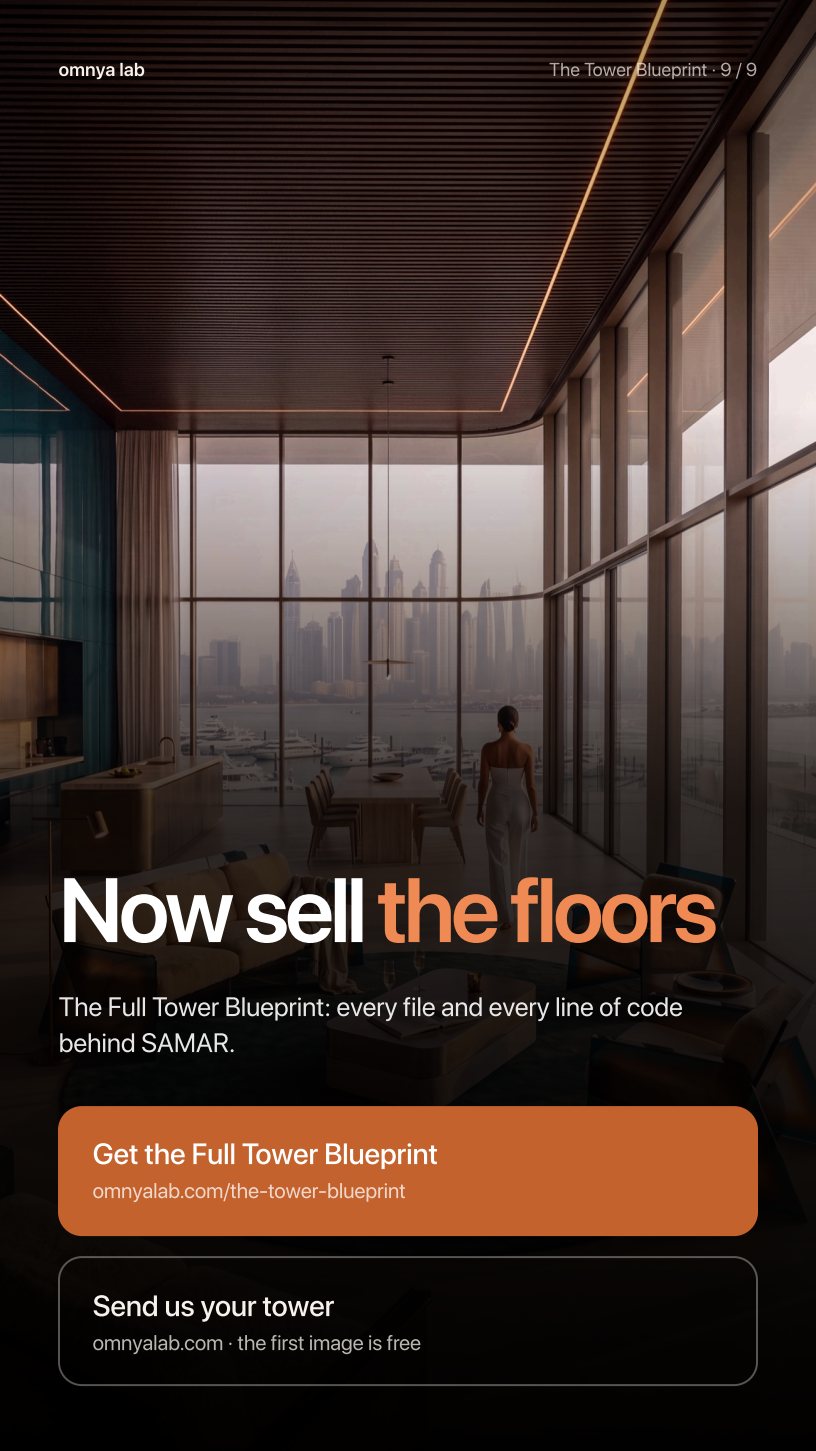

09 Rooms and hotspots

10 The return and the ending

11 Phones, where most buyers open it

12 Online, delivered, and what to charge

Plus the tower photo with every prompt: the Full Tower Blueprint.

Now sell the floors

The Full Tower Blueprint: every file and every line of code behind SAMAR.
